Instruction Scheduling

Problem: Given a set of instructions and dependencies, designate an order (find a *schedule*) satisfying the dependencies and optimizing performance

Instruction Scheduling

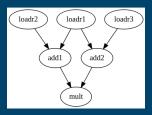

Problem: Given a set of instructions and dependencies, designate an order (find a *schedule*) satisfying the dependencies and optimizing performance

Known NP-Complete problem, practically solved by

- Heuristics
- Approximation Algorithms

Example: Dependency Graph (DAG)

```
load r1 0xFFFF
load r2 0xFFF1
load r3 0xFFF2
add r4 r2 r1
add r5 r3 r1
mult r6 r4 r5
```

Instruction Schedules

```
load r1 0xFFFF load r1 0xFFFF load r2 0xFFF1 load r2 0xFFF1 add r3 r2 r1 add r4 r2 r1 load r2 0xFFF2 add r5 r3 r1 add r4 r2 r1 mult r6 r4 r5 mult r5 r4 r3
```

- Both of the above orders (i.e schedules) are valid (i.e don't break dependencies)
- What's the difference:
 - peformance
 - number of registers used

Complication: Branching

Control flow (like loops and conditionals) complicate scheduling

 Basic Block: break code into blocks within branches (most commonly performed scheduling)

- Basic Block: break code into blocks within branches (most commonly performed scheduling)
- Global Scheduling: schedule across basic block boundaries

- Basic Block: break code into blocks within branches (most commonly performed scheduling)
- Global Scheduling: schedule across basic block boundaries
- Modulo Scheduling: an algorithm to increase pipelining of loops by interleaving different iterations

- Basic Block: break code into blocks within branches (most commonly performed scheduling)
- Global Scheduling: schedule across basic block boundaries
- Modulo Scheduling: an algorithm to increase pipelining of loops by interleaving different iterations
- Trace Scheduling: tries to optimize control flow by predicting routes taken on branches

Modulo Scheduling: Staged Loop

When performing modulo scheduling, a basic block of a loop can be broken into stages and the loop can be rolling to interleave stages between iterations

Table of Contents

Classic RISC Pipeline

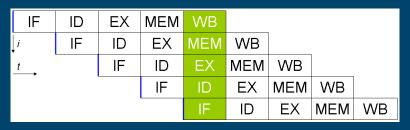

Figure: Example Pipeline

SuperScaler Pipelining

IF	ID	EX	МЕМ	WB				
IF	ID	EX	MEM	WB				
\downarrow_i	IF	ID	EX	MEM	WB			
t	IF	ID	EX	MEM	WB		_	
		IF	ID	EX	MEM	WB		
		IF	ID	EX	MEM	WB		
			IF	ID	EX	MEM	WB	
			IF	ID	EX	MEM	WB	
				IF	ID	EX	MEM	WB
				IF	ID	EX	MEM	WB

Figure: Example SuperScaler Pipeline

Out-of-order Execution

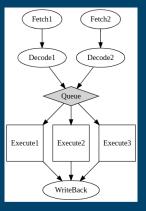

Figure: Example SuperScaler Pipeline

Out-of-order Execution

- 1. Instruction fetch
- 2. Dispatch to instruction queue
- Instruction waits until its input is available, then allowed to leave queue (in whatever order)
- 4. Instruction is executed
- 5. Results are queued
- 6. Only after all older instructions have their results written back to registers, the instruction's result is written back to registers

Hazards

- Data Hazards
 - read after write (RAW)
 - write after read (WAR)
 - write after write (WAW)

Hazards

- Data Hazards
 - read after write (RAW)
 - write after read (WAR)
 - write after write (WAW)
- Structural Hazards occurs when an aspect of hardware is accessed at the same time

Hazards

- Data Hazards
 - read after write (RAW)
 - write after read (WAR)
 - write after write (WAW)
- Structural Hazards occurs when an aspect of hardware is accessed at the same time
- Control Hazards caused by branching, next instruction unknown

Pipeline Stalls / Bubbles

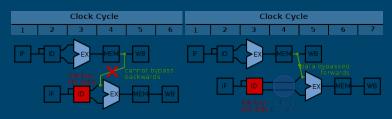

Figure: Pipeline Stall

A Ideal Schedule contains NO bubbles (often not possible)

Table of Contents

 - 3.2 Spilling
- 4. List Scheduling
- My Research
- 6. Questions?

Register Allocation

Problem: Given a schedule, assign registers keeping in mind

- limited # of registers
- can't rewrite a register until consumed by dependent instructions

Once again, known NP-Complete problem. Practically solved by using non-optimal Graph Coloring problems

Graph Coloring

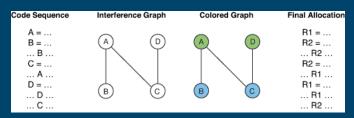

Figure: Register Allocation via Graph Coloring

Find a k-Coloring for the interference graph, where k = #Registers

• What if a k-Coloring can't be found? Must Spill memory

- What if a k-Coloring can't be found? Must Spill memory
- Simply insert new Load / Store instructions as needed

- What if a k-Coloring can't be found? Must Spill memory
- Simply insert new Load / Store instructions as needed
- Potentially creates new bubbles in the pipeline, need to re-perform scheduling

- What if a k-Coloring can't be found? Must Spill memory
- Simply insert new Load / Store instructions as needed
- Potentially creates new bubbles in the pipeline, need to re-perform scheduling
- An Ideal Schedule has no spilling

- 3. Register Allocation
 - 3.1 Graph Coloring
 - 3.2 Spilling
- 4. List Scheduling
- My Research
- 6. Questions?

List Scheduling

Simple heuristic. Choose a prioritized topological order that

- Respects the edges in the data-dependence graph (topological
- Heuristic choice among options, e.g pick first the node with the longest path extending from that node prioritized

Most commonly used method for scheduling. Efficient but yields far less than optimal schedules

Issues with List Scheduling

 Many factors to consider when constructing a schedule (everything listed in this presentation and more!)

Issues with List Scheduling

- Many factors to consider when constructing a schedule (everything listed in this presentation and more!)
- Difficult (or more accurately impossible!) to consider all these aspects into a single choice heuristic

Issues with List Scheduling

- Many factors to consider when constructing a schedule (everything listed in this presentation and more!)
- Difficult (or more accurately impossible!) to consider all these aspects into a single choice heuristic
- Combinations of heuristics can be used, and multiple iterations performed, but each will usually undo the work of the other

 - 3.2 Spilling
- 4. List Scheduling
- 5. My Research
- 6. Questions?

My Research

• Scheduling of pre-compiled binaries

My Research

- Scheduling of pre-compiled binaries
- Since pre-compiled, my algorithm can afford to be less efficient and seek near-optimal performance

My Research

- Scheduling of pre-compiled binaries
- Since pre-compiled, my algorithm can afford to be less efficient and seek near-optimal performance
- Uses a Continuous Optimization Model

Continuous Optimization

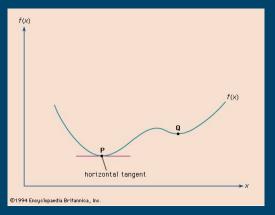

Figure: Ref https://www.britannica.com/topic/nonlinear-programming

Relaxed Continuous Optimization based Scheduling

Per Instruction i, perform a relaxation of scheduled position to dispatch and completion times t_i,b_i

${\mathbb R}$	t_i, b_i, f_i :	Objective Variables
${\mathbb R}$	II:	Constants
$\mathbb{R} o \mathbb{R}$	\mathbb{IN} :	Indicator Function
dispatch time	t_i :	
completion time	b _i :	
FIFO use $0 \le f_i \le 1$	f _i :	
#instructions iteration interval ————————————————————————————————————	II:	

Relaxed Continuous Optimization based Scheduling

Hard Constraints
$$t_i + \epsilon \le t_j$$
 $\forall i, j \cdot i \to j$ (1)
$$0 \le t_i \le b_i \le \# \text{stages} \cdot \text{II}$$
 (2)
$$b_i + \epsilon \le t_i + \text{II}$$
 (3) Objective Function $\min \sum_i (b_i - t_i + f_i) + \text{Penalties}$ (4)

Key Idea: Encode choice heuristics as penalties, adjust preference by between heuristics scaling

Relaxed Continuous Optimization based Scheduling

Other Key Idea: Need to construct penalty to prevent Spilling. Need to prevent clobbering of certain types of instructions

Solution: Indicator function to detect penalize clobbering

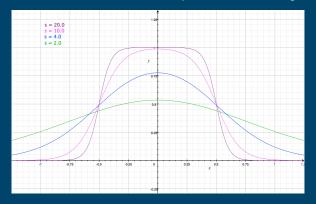

Figure: Altered Sigmoid Indicator Function
